Abstract

Necrotizing Fasciitis (NF) and sepsis shock is a rare disease in human caused by bacteria infection which is detrimental to patients. We report the diagnosis, progress, treatment and prognosis of patients with NF and sepsis shock caused by *Aeromonas hydrophila* (*A. hydrophila*). A 64 y old man was admitted for Gustilo type-iii B open fracture of the left tibia and fibula. Debridement and exopexy were carried out immediately after which he received liquid infusion and empirical antibiotic therapy in ICU. However, the condition became worse 24 h later and large extensive necrosis of the fascia and surrounding tissue was observed and the patients was in hypodynamic septic shock. Therefore, the infected limb was amputated and in the meantime, culture test for the necrotic tissue revealed presence of *A. hydrophila* and *Klebsiella*. Piperacillin and Tazobactam were applied to the patient for eliminating *klebsiella* and *A. hydrophila* respectively. Eleven weeks after admission, all blood biochemical parameter recover to normal and the patient was discharged. We present a rare case of *A. hydrophila* NF and sepsis shock in an elderly patient and suggest that resecting debridement of necrotic fascia and even limb-amputation is required for successful treatment.

Keywords: Necrotizing fasciitis, Sepsis shock, *Aeromonas hydrophila*, Excisional debridement, Amputation.

Accepted on October 16, 2017

Introduction

Aeromonas hydrophila is gram-negative bacteria and is member of the family Vibrionaceae. It is mainly found in sewage, fresh or brackish water, soil, tap water, and nonfecal organic materials [1]. They can cause variety of infections including gastrointestinal bleeding, skin and soft tissue infections, sepsis and other syndromes [2]. Thus, the understanding of the feature and treatments will be beneficial for treating them in clinic application. Necrotizing Fasciitis (NF) is a rapidly progressing fatal lesion in the skin and muscle tissue for mixed infection [3]. There are sporadic reports of cases of sepsis or necrotizing fasciitis caused by *A. hydrophila* but no case of severe infection secondary to trauma. Here we present the clinical course of a patient suffering necrotizing fasciitis and sepsis caused by *A. hydrophila* after traumatic injury. Furthermore, we used the PubMed database to search for recent case reports of infections caused by *A. Hydrophila*.

Case Report

A sixty-four-year-old man with no relevant past medical history and no previous exposure contact with aquatic animals dropped from a motorcycle in a ditch filled with stagnant water. On arriving at hospital, he was hemodynamically stable with Gustilo type-iii B open fracture of the left tibia and fibula without neurovascular impairment (Figure 1). The left leg with traumatic injury accepted debridement and exopexy

immediately (Figure 2). After operation, patient was admitted to Intensive Care Unit (ICU) and received normal saline and empirical antibiotics (amoxicillin/clavulanic acid 4 g × 4 and clindamycin 600 mg × 3) on the first day in ICU. However, 24 h later, the lesions became worse as foul smell and signs of necrotic-haemorrhagic bullae like disseminated soft-tissue infection were evident (Figure 3). Surgical exploration revealed extensive necrosis of the fascia and surrounding tissues in the wounds. Furthermore, tissue samples were dissected and wound cultures were prepared for bacteriological examination. The patient was febrile (temperature of 38.3°C) with heart pulse 128 beats/min, respiratory rate 30/min and blood pressure 83/56 mmHg. He was in hypodynamic septic shock and remained hypotensive despite administration of norepinephrine, milrinone, severe respiratory failure, signified by a PaO₂:FiO₂ ratio of 88. Laboratory results showed the following: white blood cell count 18000 cells/mm³ (normal range: 5,000-10,000 cells/mm³, 97.7% neutrophils, 2.3% lymphocytes), hemoglobin 7.6 g/dL, hematocrit 26%, platelet count 30,000/mm³, C-reactive protein above 200 mg/L, procalcitonin 10.96 ng/ml, serum creatinine kinase 807 U/L, serum myohemoglobin concentration 6577.0 ng/ml, urea nitrogen 16.9 mmol/L, serum creatinine 177 μmol/L, BNP 2882.3 pg/ml, Glu 5.7 mmol/L, total bilirubin 197.4 μmol/L, direct bilirubin 146.2 μmol/L, indirect bilirubin 51.2 μmol/L and PT/APTT/INR: 17.0/41.2/2.16.

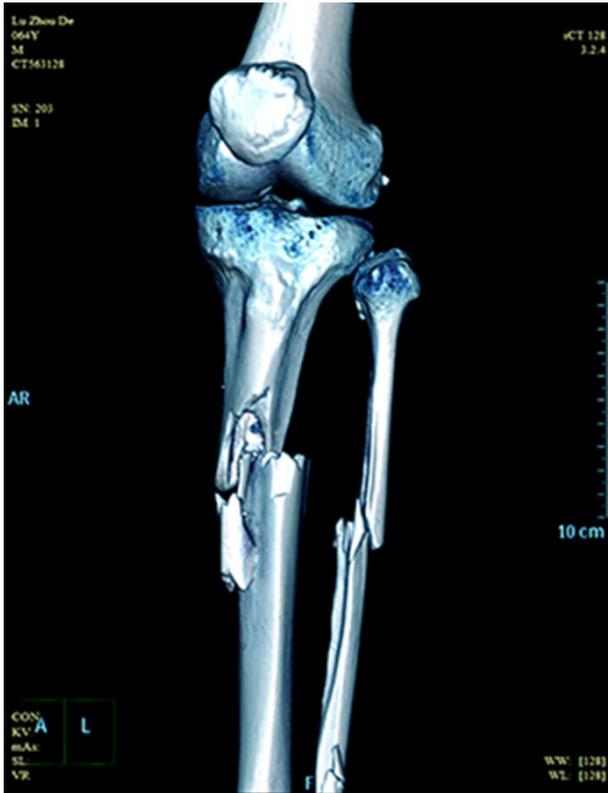

Figure 1. CT after admission.

Figure 2. Appearance of injured leg.

Patients' family initially refused amputation at higher level and the patient was brought to the operating room for revisiting the left leg, including debridement, and Vacuum Sealing Drainage (VSD). Imipenem 1.0 g \times 4 and tigecycline 50 mg \times 2 were administrated instead for antibiotic therapy after sepsis shock occurrence. After surgery, the patient remained febrile, hypotensive and oliguric renal failure with a greater demand for vasoactive medications and rising lactate concentration (from 2 mmol/l to 5 mmol/l). On the fact of obvious extremis, the family agreed and the patient received middle of left leg amputation below hip and VSD irrigation. During the surgery the patient received multiple units of packed red blood cells and fresh frozen plasma. The patient had progressive multi-organ failure and deteriorating renal function requiring hemodialysis. After 72 h, Culture test confirmed the presence of *A. hydrophila* and *Klebsiella* in wound tissues but not in blood and sputum samples. *A. hydrophila* is sensitive to

cefuroxime, cefotaxime, ciprofloxacin, gentamicin and trimethoprim but resistant to ampicillin, while *Klebsiella* is sensitive to ciprofloxacin, imipenem, amikacin, piperacillin and tazobactam but resistant to cefotaxime, ceftriaxone and ampicillin. Antimicrobial susceptibility was tested in laboratory. piperacillin and tazobactam 4.5 g \times 6 were administrated instead for antibiotic therapy based on culture test and antimicrobial susceptibility tests. Two weeks after, *Klebsiella* and *A. hydrophila* were eliminated two and three weeks, respectively later. the patient received 7 times VSD irrigation and debridement to the amputation stump until all necrotic tissue was debrided (Figure 4). In total, the patient was admitted for eleven weeks (including nine weeks in ICU) and white cell count, CRP and Procalcitonin turned normal. He can walk with crutches and move with wheelchair for short distance. The patient was discharged and followed-up at regular intervals.

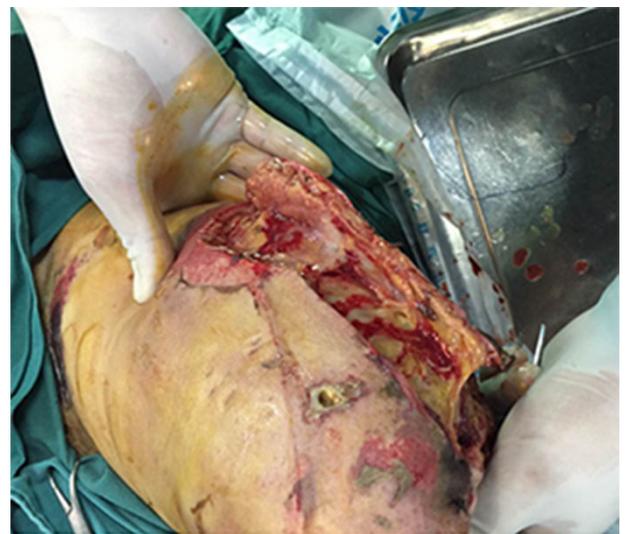

Figure 3. Examination of wounds.

Figure 4. Appearance after amputation.

Based on available literatures from PubMed Database, clinical parameters of 10 relevant cases were summarized in Table 1. There were 8 males and 2 females, with a mean age of 59 y old (30-72). Among them, eight cases suffered systemic infection with predisposing factors such as hemodialysis, immunosuppression, diabetes and chronic liver disease. Five cases were without contact history with any aquatic animal, so the infection source could be stagnant water with

Post-traumatic necrotizing fasciitis and sepsis shock caused by Aeromonas hydrophila: A case report and summary of related reports

microorganism and the infection could occur *via* traumatic penetration through tiny breaks in skin. All cases had been admitted in ICU, with mean duration of 30 d (3-63). Besides *A. hydrophila*, other pathogens were found in 4 cases. Adequate antibiotics were initially administered for empiric therapy and excisional debridement of the necrotic fascia or immediate limb amputation was performed early to all patients. However, 8 patients recovered while 2 patients died finally.

Discussion

Aeromonas hydrophila are gram-negative bacilli commonly found in aquatic environments [4], such as stagnating, streaming surface water, wells and even swimming pool [5]. They can also cause diseases in humans including gastroenteritis, water-associated traumatic wound infections including necrotizing fasciitis, meningitis, peritonitis, and bacteremia [6]. Necrotizing Fasciitis (NF) is a deadly necrotic inflammation of skin, soft-tissues, and muscle bundles [7]. The mechanism has been found to be accounted for *A. hydrophila* infection, which is injury of soft skin tissue, and leading to sepsis and secondary necrotizing fasciitis [8].

We analysed *A. hydrophila* infection in soft skin tissue in the present case and summarized that in previous reported cases. Most of these patients can be considered immunosuppressed to some degree because of certain medical conditions, such as

hemodialysis, immunosuppression, diabetes and chronic liver disease. The mechanism responsible for the severe course of *A. hydrophila* infection involves production of highly toxic exotoxins, such as ascytolysin, hemolysin, cytotoxic enterotoxin, and cholera toxin-like factor [9]. In the 10 cases summarized, only 5 cases (half of ten) were infected through wound exposure and necrotizing fasciitis attributable to *A. hydrophila* were believed to develop only in an immunocompromised host. And in this sense, sepsis shock, a most invasive form of infection, may be also as a result of immunocompromising in the presence of infection.

Necrotizing fasciitis and sepsis caused by *A. hydrophila* were associated with high mortality, thus early surgical intervention was essential [10]. Some investigators have reported that *A. hydrophila* infection can cause severe necrotizing fasciitis and myonecrosis. Early and aggressive surgical intervention must be applied immediately after necrotizing fasciitis is diagnosed as patients could die due to delayed surgical removal of necrotic lesions (including amputation) [11,12]. For our patient, broad-spectrum antibiotics were administered within one hour after sepsis was identified and aggressive multi-modality treatments together contributed to patient's prognosis. Including our patients, among the ten cases summarized patients were benefit to receiving excisional debridement of the necrotic fascia or early limb amputation.

Table 1. Clinical parameters of patients with *A. hydrophila* infection.

Patient no.	Patient 1 [13]	Patient 2 [14]	Patient 3 [15]	Patient 4 [16]	Patient 5 [17]
Sex, age	M, 55	M, 58	M, 60	M, 63	M, 61
Infection site	Blood Dialysis catheter	Blood Wound	Wound	The lower left leg	Epiglottitis Neck soft tissue Rectum
Type of infection	Sepsis	Necrotizing, fasciitis	Necrotizing, fasciitis	Ecthyma gangrenosum	Necrotizing fasciitis Soft tissue infections
Disease/risk factors	Kidney-failure, hemodialysis, immunosuppressive agents	None	Cirrhosis Type-two diabetes	Diabetes, obese Hypertensive cardiopathy	Cirrhosis
Contacting, history/rural setting	None	Stagnant water	None	Stagnant water in well	None
ICU-days	14	49	3	60	21
Other pathogens		<i>Pseudomonas aeruginosa</i>	None	None	None
Initial drug (antibiotics)	Piperacillin Tazobactam	Clindamycin Cefuroxime	Piperacillin Tazobactam	Meropenem Tigecycline	Ceftriaxone, Clindamycin, Ciprofloxacin
Operation/treatment	Dialysis catheter removal	Amputation followed by right hip	Fasciectomy Debridements	Hyperbaric oxygen chamber therapy Skin grafting Surgery	Tracheostomy, Fasciotomy, Debridement

Outcome	Recovered	Died	Died	Recovered	Recovered
Patient no.	Patient 6 [18]	Patient 7 [19]	Patient 8 [20]	Patient 9 [21]	This report
Sex, age	F, 72	M, 66	M, 30	F, 60	M, 64
Infection site	Blood, bile	The right foot	Lung	Breast	Left leg
Type of infection	Cholecystitis; blood stream infection	Necrotizing, fasciitis	Fulminant pneumonia	Cellulitis, abscess	Necrotizing, fasciitis
Disease/risk factors	Rheumatoid arthritis, acute suppurative cholangitis	Diabetic gangrene, renal failure, haemodialysis, liver cirrhosis, hepatocellular carcinoma	Cardiac aspiration pneumonia	Breast Reconstruction, leech therapy	None
Contacting, history/rural setting	Endoscopic retrograde cholangiopancreatography	None	Stagnant water	None	Stagnant water
ICU-days	18	49	27	3	63
Other pathogens	<i>Klebsiella pneumoniae</i>	None	<i>Streptococcus</i>	None	<i>Klebsiella pneumoniae</i> , <i>Enterococcus faecalis</i>
Initial drug (antibiotics)	Piperacillin, tazobactam	Clindamycin, minocycline	cefuroxime, Piperacillin, tazobactam, levofloxacin	Ciprofloxacin, vancomycin, aztreonam	Tienam, tigecycline
Operation/treatment	Laparoscopic cholecystectomy	Right, leg amputation	ECMO	Implant removed, debridement	Amputation followed by left hip, VSD debridement
Outcome	Recovered	Recovered	Recovered	Recovered	Recovered

Conclusions

In conclusion, together with previous study, a general treatment against *A. hydrophila* infection can be arrived. And the empiric Antibiotics which should be used started in cases of suspected necrotizing fasciitis before treatment. Firstly, rapidly progressing of soft-tissue infection could indicate *A. hydrophila* infection. Secondly, aggressive antibiotic drugs were essential to administered for empiric therapy. Thirdly, early diagnosis of all forms of *A. hydrophila* infection is of significance, especially in the case of necrotizing fasciitis and sepsis. Fourthly, amputation, debridement and VSD irrigation in combination with appropriate antibiotic treatment should be applied for good prognosis.
